Case Study of Hive using Hadoop

Abstract -Hadoop is a framework of tools. It is not a software that you can download on your computer. These tools are used to running applications on big data which has huge in capacity,need to process quickly and can be in variety forms. To manage the big data HIVE used as a data warehouse system for Hadoop that facilitates ad-hoc queries and the analysis of large datasets stored in Hadoop .Hive provides a SQL-LIKE languages called HIVEQL. In this paper we explains how to use hive using Hadoop with a simple real time example and also explained how to create a table,load the data into table from external file ,retrieve the data from table and their different statistics like CPU time for each stage of query execution ,cumulative CPU time and time taken to fetch records.

1. INTRODUCTION

1.1. Hadoop

Hadoop is a open source and is distributed under Apache license. It is a framework of tools and not a software that you can download. These tools are used to running applications on big data .Big data means data with respective to its volume, speed, variety forms(Unstructured).In traditional approach big data is processed by using powerful computer but this computer will do good job until some limit,because computer is not scalable. It process according to its processor(core) type and speed,memory capacity.

Hadoop takes different approach (Fig 1)than its traditional approach. It breaks the data into smaller pieces .

Breaking the data into smaller pieces is good idea but how about computation?
Computation is also broken into pieces i.e processed into different levels/nodes and result will be combined together.

Fig.1.

A.MapReduce   B. File System(HDFS).
One important characteristic of Hadoop is that it works on Distributed model and it is Linux based set of tools .
All the Machines or nodes under Hadoop will have two components .
A. Task Tracker(T)[1] [2] B. Data Node(D)[1][2].(Fig 2)
The job of task tracker is to process the task given to particular node and the job of data node is manage the data given to particular node .The nodes which process the piece of data and has task tracker and data nodes are called slaves. Above these slaves there will be a master which has additional components called 1.Job Tracker(J) [1][2]2.Name Node(N)[1][2].**(Fig 2)**
Job Tracker and Task Tracker are comes under MapReduce.
Data Node and Name Node are comes under HDFS

Fig. 2.

At the highest level it has a simple architecture which breaks the data and computation into pieces .Hadoop has two important components .

1.2. HIVE

Hive is a Data warehouse system layer built on Hadoop. It allows to define a structure for unstructured big data. It simplifies ,analysis and queries with an SQL like scripting language called HIVEQL.

Hive is not Relational Database,it uses a database to store meta data,but the data that hive processes is stored in HDFS.

Hive is not designed for on-line transaction processing(OLTP).Hive runs on Hadoop which is a Batch-processing system where jobs can have high latency with substantial overhead. Therefore latency for hive queries is generally high even for small jobs. Hive is not suited for real-time queries and row level updates and it is best used for batch jobs over large sets of immutable data such as web logs.

2. THE TYPICAL USE CASE OF HIVE

Hive it takes large amount of unstructured data and place it into a structured view as shown in Fig.3.,that can be used by business analysts by the business tools. Hive supports use cases such as Ad-hoc queries,summarization,data analysis.

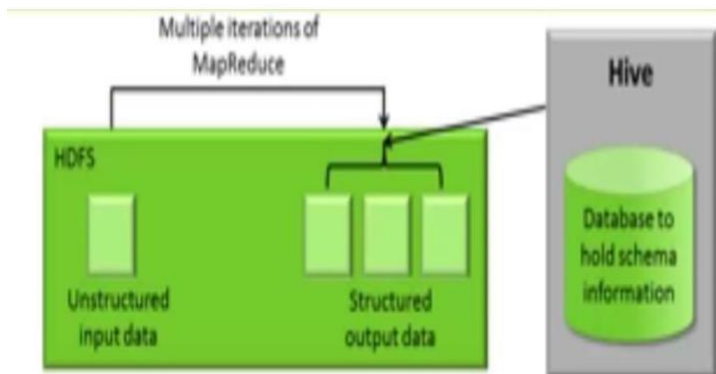

Fig.3.

HIVEQL can also be exchange with custom scalar functions means user defined functions(UDF ' S),aggregations(UDFA's) and table functions(UDTF's).

3. HIVE ARCHITECTURE

As shown in Fig.4 . Hive Architecture consists of

A. Meta store
It stores schema information and provides a structure to stored data .
B.HIVEQL
Which is for query processing,compiling,optimizing and execution ,those queries turned into MapReduce job which invokes mapper and reducer for processing. HIVEQL is similar to other SQLs ,it uses familiar relational database concepts(tables,rows,columns,schema),it is based on the SQL-92 specifications. Hive supports multi-table inserts via the code means big data can be accessed via tables. It converts SQL queries into MapReduce jobs. User does not need to know MapReduce. Also supports plugging custom MapReduce scripts into queries. C. User Interface

Hive can be approached by number of user interfaces. It has web UI,it has own command line interface and can be accessed using HDInsight.

Hive is good choice when you want to query the data,when you need an answer to specific questions if you are familiar with SQL.

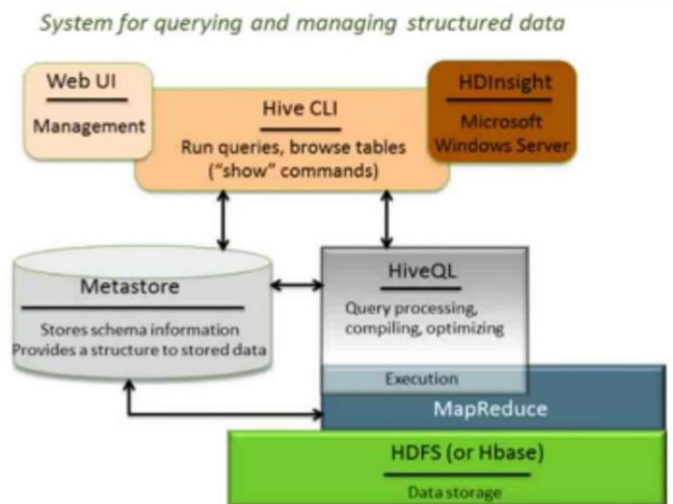

Fig.4.

4. USING OF HIVE WITH HADOOP.

A .Prerequisites to work with Hive

The prerequisites for setting up Hive and running queries are
1.User should have stable build of Hadoop
2.Machine Should have Java 1,6 installed
3.Basic Java Programming skills
4.Basic SQL Knowledge
5.Basic Knowledge of Linux
To start Hive first start all the services of Hadoop using the command **$ start-all.sh.** Then check all services are running or not using JPS command ,if all are services are running then Use the command $ **hive** to start HIVE

B.HIVE TABLES

Here we are explaining about basics of Hive Tables.

A Hive table consists of
Data: It is typically a file or group of files in HDFS.
Schema:It is in the form of meta data stored in a relational database. Schema and data are separate .A schema can be defined for existing data. Data can be added or removed independently. You have to define a schema if you have existing data in HDFS that you want to use in Hive

C. Managing Tables

See current tables
hive>Show Tables;

Check the schema
hive>Describe mytable;

change the table name
hive> ALTER TABLE mytablename RENAME to mt;

Add a Column
hive>ALTER TABLE mytable ADD COLOUMNS (mycol STRING);

Drop a Partition
hive >ALTER TABLE mytable DROP PARTITION(age=17)

D. Loading Data

Use LOAD DATA to import data into Hive Table
hive>LOAD DATA LOCAL INPATH ' path of input data' INTO TABLE mytable;
The files are not modified by Hive. Use the word OVERWRITE[3][4] to write over a file of the same name. Hive warehouse default location is /hive/warehouse. Hive can read all of the files in a particular directory. The schema is checked when the data is required and if a row does not match the schema,it will be read as null.

E. Insert
Use INSERT[3] statement to populate data into a table from another HIVE table. Since query results are usually large it is best to use an INSERT clause to tell HIVE where to store your query.
Example:
hive>CREATE TABLE age_count(name STRING,age INT); hive>INSERT OVERWRITE TABLE age_count
                SELECT age,COUNT(age)
                FROM mytable;

F. Performing Queries
SELECT statement is used for this. It supports the following:
Where clause
UNION ALL and DISTINCT
GROUP BY and HAVING
LIMIT clause
Can Use REGULAR EXPRESSION Column Specification

5.   CASE STUDY

  In this we are giving a real example how to use HIVE on Top of the HADOOP and different statistical analysis. In this example we have a predefined dataset (cricket.csv) having more than 20 columns and more than 10000 records in it. In the below example we are explaining how to display few records based on attributes of cricket.
 The cricket.csv file has different attributes like name,country,
Player_iD,Year.stint,teamid,run,igl,D,G,G_batting.AB,R,H,2 B,3B,HR,RBI,SB,CS,BB,SO,IBB,HBP,SH,SF,GIDP,G_OLD

Follow the below steps in order to retrieve the data from Big tables.
1.Start Hadoop
$ start-all.sh

2.Create a Folder and copy all predefined datasets
$ hadoop fs -mkdir sampledataset

$ hadoop fs -put /home/sai/hivedataset/ /user/sai/sampledataset

Note:hivedataset has Big Data tables in .cs format ,those tables are copying from my local file system to Hadoop.

3.Start Hive
$ hive

4.Create Table in Hive
hive>create table temp_cricket (col_value STRING);

5.Load the Data from csv file to table temp_batting hive> LOAD DATA INPATH '/user/sai/sampledataset/hivedataset/cricket.csv' OVERWRITE INTO TABLE temp_cricket;

6.Create Another table to Extract data
hive>create table batting (player_id STRING, year INT, runs INT);

7.Insert data Into newly created data By extracting hive>insert overwrite table batting SELECT regexp_extract(col_value, '^(?:([^,]*)\,?){1}',3) player_id, regexp_extract(col_value, '^(?:([^,]*)\,?){2}', 4) year, regexp_extract(col_value, '^(?:([^,]*)\,?){9}', 7) run from temp_cricket;

In above query from temp_cricket table player_id,year,run are loaded into batting table .

Execute Few Queries and observe the result

Example 1
Display year and maximum runs scored in each year

hive> SELECT year, max(runs) FROM batting GROUP BY year;

Total Jobs=1
hadoop job information for stage-1:
Number of mappers:1;Number of reducers:1 Stage-1 map=0% reduce =0%
Stage-1 map=100% reduce =0% cumulative CPU 3.45 sec
Stage-1 map=100% reduce =100% cumulative CPU 6.35 sec
MapReduce Total cumulative CPU time:6.35 sec
Time taken :46.09 sec

Example 2

Display player_id,year and maximum runs scored in each year

hive>   SELECT a.year, a.player_id, a.runs from batting a
         JOIN (SELECT year, max(runs) runs FROM batting
         GROUP BY year) b
          ON (a.year = b.year AND a.runs = b.runs) ;

Total Jobs=2
Launching job 1 out of 2
hadoop job information for stage-2:
Number of mappers:1;Number of reducers:1
Stage-2 map=0% reduce =0%
Stage-2 map=100% reduce =0% cumulative CPU 3.0 sec
Stage-2 map=100% reduce =100% cumulative CPU 5.95 sec
MapReduce Total cumulative CPU time:5.95 sec

Launching job 2 out of 2
hadoop job information for stage-3:
Number of mappers:1;Number of reducers:0
Stage-3 map=0% reduce =0%
Stage-3 map=100% reduce =0% cumulative CPU 3.12 sec

Stage-3 map=100% reduce =100% cumulative CPU 3.12 sec
MapReduce Total cumulative CPU time:3.12 sec
Time taken :65.743sec
As there are two queries (Select Statements) two jobs have
been executed. The CPU time varies according to the system
configuration

CONCLUSION

Hive works with Hadoop to allow you to query and manage
large-scale data using a familiar SQL-like interface. Hive
provides command line interface to the shell and Microsoft
HDInsight provides console access. Hive tables consist of
data and schema and they are separated for maximum
flexibility. Hive Query Language(HIVEQL) supports familiar
SQL operations including joins,sub queries,Order By,Sort by
etc. The CPU analysis depends on Hadoop configuration
nodes and System configuration
